Jandy error codes

Onboard diagnostics or OBD/OBD-II codes are those dreaded engine error codes that only trained auto mechanics seem to understand. Take a few minutes to gain a greater understanding of car engine error codes and the next time the check engine light comes on, you'll know exactly what to expect. A Bit About the Check Engine Light Check engine light problems are just the beginning when it comes to OBS or OBS-II codes that auto mechanics use to determine what is wrong with your car or truck. The check engine light means that vehicle check engine codes have popped up in your vehicle's diagnostic menu. Late-model cars and trucks run a quick diagnostic report as soon as you start the engine and contain one or more computers that monitor sensors throughout the vehicle constantly. From ignition system sensors to fuel injections sensors, those onboard computers work hard to maintain your vehicle. When an error in a sensor occurs, that check engine light pops up to let you know. The Common Check Engine Code p0171 Common Mercedes check engine light codes are the same as codes for many other vehicles. One of the most common of these light codes is the check engine code p0171. The check engine light comes on, you take your vehicle to an auto mechanic, and he or she hooks the car up to an OBD or OBD-II scanning tool. This tool finds the code, and the code tells everyone what's wrong with your car. The internal combustion engine runs most efficiently when the fuel and air mixture is just right. When the mixture is too rich or too lean, the check engine code p0171 lets you know that a control module needs to be changed, the software requires updating, your fuel filter is clogged or your fuel pump is weak. Check Engine Code P0128 Another very common of the vehicle check engine codes is the check engine code P0128. When your check engine light brings this code to your attention, you'll need a little help maintaining or achieving the proper engine temperature. To work efficiently, your vehicle's engine has to be at the right operating temperature. The check engine code P0128 lets you know that you might have a defective thermostat, engine coolant temperature sensor or cooling system. With this engine code, you might also have low or dirty engine coolant or a fan that is not running correctly. A quick repair saves your vehicle's engine from temperature-related damage. The Key to Understanding Check Engine Codes There is a simple system that helps you to understand which part of the vehicle each OBD or OBD-II code represents. An OBD or OBD-II code begins with a letter. The letter stands for the portion of the vehicle that requires your attention. For example, if the code begins with the letter P, this code is concerned with the powertrain of the car. Codes that begin with U are for the network while B codes refer to the body. The Tool to Reset My Check Engine Light Want to take care of your own check engine light problems? Grab an OBD scanning tool, plug it into your vehicle, find and fix the broken part and reset your check engine light. There are plenty of car diagnostic tools that are ideal for the do-it-yourself mechanic. Check out scanning tools by Foxwell, BlueDriver Professional or TryAce for at-home car repairs. These scanning tools use Bluetooth or a corded plug that attaches to your car to scan for check engine codes and narrow down those vehicle problems. Several versions of the OBD scanning tool are available for less than \$200. MORE FROM QUESTIONSANSWERED.NET Bosch washers are amazing appliances — until an error code pops up and they don't work as they should. Fortunately, some error codes may have simple solutions you can do on your own. Check out below for some common Bosch error codes and their possible fixes. Error Code E02 or E2 and Water Supply Problems If you see an E02 or an E2 error on a Bosch front-loading washing machine, you're probably dealing with a problem relating to the machine's water supply. These error codes are essentially telling you the machine isn't able to fill itself with water when the wash cycle is beginning. If the machine is filling with water, the machine is telling you the process is taking longer than it should, giving you this error. Check your home's water pressure make sure the problem isn't within the home versus the machine. Next, check that the machine water supply is actually turned on. If it is, check the water hose to make sure it's not damaged. Error Code E13 and Drainage Issues If you see an E13 error pop up on the machine, you're most likely dealing with a drainage problem. Turn off the machine's power, and unplug the washer from the wall before you do anything. You're going to need to follow the detailed instructions in the machine's manual to get to the drain trap and lint filter. Once there, you'll be able to pull out whatever's clogging the machine. Remove the blockage and run a load of laundry while leaving the pump access door off. This way you can ensure the cap is back on properly and there are no further leaks. E17 Error Code and a Locked Machine If you see the E17 error code while your clothes are still inside the machine, you're most likely experiencing the machine locking itself up, preventing you from taking your clothes out of the machine as well as preventing the water from emptying. One quick fix for the E17 code is to take the machine and slowly tip it backwards. This will allow the water to slowly drain away from the sensor, which will then make the machine door open. Error 5 or Error 6 and Water Temperature Issues If you notice that an Error 5 or Error 6 code has popped up, it means the machine's water temperature sensor is defective. Unplug the washer. When you're certain it's unplugged, take a look at the washer temperature sensor and reconnect any loose wires. If you notice the wire harness is damaged, replace it. If all of the other connections are okay, reconnect the water sensor. If the problem persists, reach out to a Bosch repairman. Error 14 and the Overflow Level If you see error code 14, that code means the machine is sensing the overflow level has been reached. If that's not the case, it probably means the machine water level pressure switch is broken and will have to be replaced. If it's overfilled, shut off the water supply faucet immediately. When this error code is activated, the drain pump runs immediately, emptying out the water. This should prevent the machine from continuing to fill and eventually flooding your space. MORE FROM QUESTIONSANSWERED.NET Hello! Thanks in advance for all replies / help. I'm desperately looking for assistance with my Aquapure 1400 system. Towards the beginning of last season I got some error codes. I believe it was the 125/194 codes (could be wrong on this). I clean my salt cell at the end of every season, and everything was pointing to the sensor that I read online. So I ordered a new port sensor from Amazon (it came with a new sensor indicator module Amazon.com : Zodiac R0452500 16-Foot Port Sensor with O-Ring Replacement Kit for Select Zodiac Jandy PureLink AquaPure Water Purification System : Swimming Pool Chlorine Alternatives : Patio, Lawn Garden) and all was good for a little bit. At the end of last season I started getting the 125/194 error codes. 194 Cell Current is 85% lower than desired and cell voltage above 19V (Generates 125 code - Cell dirty or needs replacement) 125 Cell needs to be cleaned Since last summer in the NY metro was a lot hotter than normal I had bumped my chlorine production to 85% to maintain balance. I figured I was getting the 194 low current, which generated the 125, which was due to the cell being dirty. So since it was the very end of the season when I started getting the codes I cleaned the cell out (which was dirty) and closed the pool. I opened the pool up for this season and I immediately got the service warning again w/ the 194 and 125 service codes. Then the code would go away. Then the code would come back as 123. 123 Extremely low current to cell Then it would go away, and eventually come back as 194 and 125. I can follow directions very well if I know where to begin but at this point I'm lost. Is it a bad cell? Is it a bad circuit board? The pool was built in 2007, and I think that all the equipment is original (I bought it in 2015). The salt cell has a S/N of D11GH0251 so if what I've been reading correctly it was replaced in 2011. Is that it? Is there any way to be sure? I am about to rip it out and double check it but I didn't see anything wrong with it when I cleaned it. For background info the pool is 30k gallon, and the pump runs about 10/11 hours a day, and it's usually open from just after memorial day to just after labor day => Thanks! All of the codes indicate that the cell has worn out and needs to be replaced. There are some voltage readings that you can take that will confirm that the cell needs to be replaced and the directions are located in documents that can be found online. Google Jandy AquaPure Workbook and you should be able to find it. Some of the better ones will have a flow chart to follow. Thank you. I followed the steps w/ the multi meter and got interesting results. When I first took the circuit board and placed the leads from the multi meter to it I was receiving a steady 15.5 vdc. Then I moved the leads to the salt cell and got a fluctuating 10-38 vdc. This was w/ the Jandy set for 100% chlorination and cell on. I received error code 123 in this situation. Then I repeated the test (killed the breaker, turned it back on) to make sure I got the same results and that I had good contact on the board. I got a steady 37.5 vdc on the board and 37.3 at the cell. This then generated code 125. Is this still something I should buy a new cell for? Is this the board? Is there anything else to check before I spend \$480 on a cell? If I have to I have to, I just don't want to spend that and then find out it's the board. Thanks!!!!!! Hard to tell but it looks like it probably needs a new cell. 123 can happen from low salt. Do you have enough salt? I believe measuring from the board and assuming the unit is set to 100%, you should get a steady voltage reading. I also believe 37 at the cell is high and indicative of replacement. Someone else probably know better. You can get the kit with cord cell and sensor for under 500. Just make sure its the new style sensor with the plastic box. From what you are getting I would say the cell needs to be replaced. Follow robj5's advice and get a cell, new style sensor, and power cord. Definitely not salinity, my meter shows 3.4 gpl, and the pool store showed 3200 ppm on the electronic meter and 3000 on their strips. Ok great. I'll replace the whole cell. Thanks, guys!!! Guys, I replaced the salt cell and let it run a few days before jumping to conclusions that it worked. However, it was completely successful. Thanks!!!! Hey guys, I also have a Aquapure 1400, and am receiving the 123 error code. I recently replaced the cell/cord/sensor because I thought the cell was going bad (about 3yrs. old). I don't think I am getting any reading at all with my multimeter at the cell? Does this mean the circuit board needs to be replaced, if so, which one? Thanks! Make sure there aren't any other codes that flash other than 123. Check the DC cord for damage, that is the one that connects to the cell. Make sure all the pins are tight. Check the cell for scale and clean if required. Report back what you find. Hi allarena...curious to know how is your new cell working...I was gettogether ng exactly the same error codes and replaced my entire salt cell kit (bought it from amazon). Worked fine for a few days. The. I started getting 120/121 codes. My chlorine levels are good though. Thanks Ping, I haven't seen any other codes that flash other than 123. The cell/cord/sensor is only about a week old. I will double check to make sure the pins are tight. I don't believe I am getting any voltage to the cell though. Make sure you check the cell size 700 or 1400 and the system is set for that sized cell. Hey Ping, I have the 1400 model. I checked the pins and also tested the board where the green & blk/wht wires connect (cord from the cell) and only get 0.0. All other board tests pass. I did just receive a 145 error code (reading the salt at 5300, I normally keep the salt at 3200-3400 and haven't added salt for two years). I recalibrate the salt to 3500 for now. (although I realized I never ordered a new salt kit this summer from TFT when I ordered my TF-100 refill kit, so I have that ordered to check the proper salt level, my 1.5yr. old TFT salt kit reads 4000, which I have a feeling is high from the old chemicals?), and I get the 123 error code back. Do I need a new main board? I see amazon has two boards, a front (which looks like the one I have) and a back circuit board (which I don't think I have one?). Thanks for helping me!!!! I came on to the forum looking for answers and read Allarena's post - I have exactly the same thing going on now. It's been a hot summer and I've been running 100%. 123, then 125/194. Cell is clean, pool chlorine levels have been dropping. Voltage tests showed same as his. My cell is only 3 years old, I take very good care of it. Question is: These cells are in the range of \$500+. Not chump change. I occasionally see this blue Compupool cell that says it's a direct replacement, and it costs \$359. Does anyone have any experience with it? Thanks.
